

On lepton pair production in proton-antiproton collisions at intermediate energies and the main backgrounds.

A. Skachkova (JINR, Dubna) for PANDA collaboration.

This intermediate energy experiment ($E_{beam} < 15$ GeV) may play an important role, because it allows to study the energy range, where the perturbative methods of QCD (pQCD) come into interplay with a rich physics of bound states and resonances. The physics of hadron resonances formation and decay is strongly connected with the confinement problem, i.e. with the *parton dynamics* at large distances [1]. A detailed and high-precision experimental study at PANDA may allow to discriminate between a large variety of existing nonperturbative approaches and models that already exist or are under development now. Dilepton events may serve as a powerful tool to get out the *information about the parton distribution functions (PDFs)* in hadrons [2]. The plans to study this process are included into the Lol and TPR of PANDA experiment at HESR. This study may provide an interesting *information about quark dynamics inside the nucleon*.

The results of study of leptons angle and energy spectra distributions, based on this Monte-Carlo simulation, was used for a proper "geometrical" design of PANDA muon system.

In the following we consider the case of antiproton beam energy $E_{beam} = 14$ GeV which corresponds to the center-of-mass energy of the $\bar{p}p$ system $E_{cm} = 5.3$ GeV.

MMT-DY process

V.A. Matveev, R.M. Muradian, A.N. Tavkhelidze (MMT) (V.A. Matveev, R.M. Muradian, A.N. Tavkhelidze, JINR P2-4543, JINR, Dubna, 1969; SLAC-TRANS-0098, JINR R2-4543, Jun 1969; 27p.)
 process, called also as "Drell-Yan process"
 (S.D. Drell, T.M. Yan, SLAC-PUB-0755, Jun 1970, 12p.; Phys.Rev.Lett. 25(1970)316-320, 1970)
 The dominant mechanism of the l^+l^- production is the perturbative QED/QCD partonic $2 \rightarrow 2$ subprocess
 $q\bar{q} \rightarrow \gamma^*/Z \rightarrow l^+l^-$
 $\sigma = 5.6 \cdot 10^3$ pb (about 7×10^6 events per 1 year for $L = 2 \cdot 10^{32} \text{cm}^{-2} \text{s}^{-1}$)

J/psi production (benchmark process)

The main contributions to the cross section give the following processes:
 $q\bar{q} \rightarrow \gamma^* \rightarrow c\bar{c} \rightarrow J/\psi \rightarrow l^+l^- + X$
 $q\bar{q} \rightarrow c\bar{c} [^3S_1(0)] g \rightarrow l^+l^- + X$
 $q\bar{q} \rightarrow c\bar{c} [^3P_J(0)] g \rightarrow l^+l^- + X$
 Another considered subprocesses are:

- 421) $g\bar{g} \rightarrow c\bar{c} [^3S_1(0)] g \rightarrow l^+l^- + X$
- 422) $g\bar{g} \rightarrow c\bar{c} [^3P_J(0)] g \rightarrow l^+l^- + X$
- 423) $g\bar{g} \rightarrow c\bar{c} [^1S_0(0)] g \rightarrow l^+l^- + X$
- 424) $g\bar{g} \rightarrow c\bar{c} [^1P_1(0)] g \rightarrow l^+l^- + X$
- 425) $g\bar{g} \rightarrow c\bar{c} [^3S_1(0)] q \rightarrow l^+l^- + X$
- 426) $g\bar{g} \rightarrow c\bar{c} [^3P_J(0)] q \rightarrow l^+l^- + X$
- 427) $g\bar{g} \rightarrow c\bar{c} [^1S_0(0)] q \rightarrow l^+l^- + X$
- 428) $g\bar{g} \rightarrow c\bar{c} [^1P_1(0)] q \rightarrow l^+l^- + X$
- 429) $g\bar{g} \rightarrow c\bar{c} [^3S_1(0)] q \rightarrow l^+l^- + X$
- 430) $g\bar{g} \rightarrow c\bar{c} [^3P_J(0)] q \rightarrow l^+l^- + X$
- 431) $g\bar{g} \rightarrow c\bar{c} [^1S_0(0)] q \rightarrow l^+l^- + X$

Backgrounds to the $\bar{q}q \rightarrow \gamma^* \rightarrow l^+l^-$ process

The simulation was done at the level of PYTHIA6.4 (without account of magnetic field and detector effects) in approximation that particles are allowed to decay in cylinder volume $R=2500 \times L=8000$ mm

1-st source - leptons from hadronic decays in the same $p\bar{p}$ process

2-nd source - Background QCD processes

The generation was done with the use of more than 20 QCD subprocesses existed in PYTHIA6.4 (including the signal one $q\bar{q} \rightarrow \gamma^* \rightarrow l^+l^-$).

The main contributions come from the following partonic subprocesses:

- $q + g \rightarrow q + g$ (gives 50% of events with the $\sigma = 4.88$ mb);
- $g + g \rightarrow g + g$ (gives 30% of events with the $\sigma = 2.96$ mb);
- $q + q' \rightarrow q + q'$ (gives 18% of events with the $\sigma = 1.75$ mb);
- $q + \bar{q} \rightarrow g + g$ (gives 0.6% of events with the $\sigma = 5.89 \cdot 10^{-2}$ mb);
- $q + \bar{q} \rightarrow l^+ + l^-$ (signal process gives 0.00005% of bkgd events, due to $\alpha = 5.02 \cdot 10^{-6}$ mb);

So, initially there is 1 signal event among 2,000,000 of QCD background i.e., initially $\rightarrow S/B = 5.5 \cdot 10^{-6}$

3-d source (the most difficult) - Minimum-Bias processes:

Some examples:

- Low - PT scattering (gives 68% of events with the $\sigma = 34.25$ mb);
- Single diffractive (gives 6% of events with the $\sigma = 3.32$ mb);
- $\bar{p} + q \rightarrow l^+ + l^-$ (gives 0.000012% of events, $\sigma = 5.9 \cdot 10^{-6}$ mb);

So, we have 1 signal event against 8,333,333 of Mini-bias bkgd $\rightarrow S/B = 10^{-7}$

Mini-bias background is 5 times harder than QCD background

Cuts for separation of background events

1. selection of events with the only 2 leptons, having $E_l > 0.2$ GeV, $P_{Tl} > 0.2$ GeV;
2. these 2 leptons have charges of the opposite charge;
3. the vertex of lepton origin lies within the $R < 15$ mm from the interaction point;
4. $M_{inv}(l^+l^-) \geq 0.9$ GeV;
5. leptons have to satisfy the isolation criteria: the summed energy of particles $E_{sum} < 0.5$ GeV within the cone of $R_{isolation} = \sqrt{\Delta\eta^2 + \Delta\phi^2} = 0.2$.

The first 3 cuts, being applied to the sample of signal events, can allow one to select a subsample which include a strongly reduced fraction (fr) of events, containing fake leptons ($fr_e = 0.008\%$ for the case of e^+e^- production and $fr_\mu = 0.001\%$ for the $\mu^+\mu^-$ production). The loss of the signal events due to application of cuts 1) - 3) is about = 17% for $\mu^+\mu^-$ and = 14% for e^+e^- production.

Efficiency of cuts in the presence of mini-bias and QCD background & S/B ratio

N of cuts	S/B for $\mu^+\mu^-$ production	Efficiency	S/B for e^+e^- production	Efficiency
1	$1.41 \cdot 10^{-5}$	0.007	$5.34 \cdot 10^{-4}$	$1.78 \cdot 10^{-4}$
2	$2.12 \cdot 10^{-5}$	0.665	$5.41 \cdot 10^{-4}$	0.98
3	$9.94 \cdot 10^{-5}$	0.002	$5.47 \cdot 10^{-4}$	0.99
4	0.123	0.08	$9.27 \cdot 10^{-2}$	0.006
5	Background = 0	-	3.8	0.024

The total loss of signal events after application of all five cuts is expected to be about 25%.

So, we can expect to gain a huge sample of about 7×10^6 signal dilepton events per 1 year (10^7 sec).

Parents of background leptons

The most probable parents of fake electrons \rightarrow are neutral pions ($\pi^0 \rightarrow e^+e^- \gamma$)
 muons \rightarrow are charged pions

The most probable grandparents of fake electrons \rightarrow are strings (Lund model), $\rho, \eta, \omega, \Delta^0, \Delta^+$

muons \rightarrow are strings (Lund model), ρ^+, ρ^-, ω

Lepton (e) isolation criteria

The plots show the distributions over the summarized energy of the final state particles in the cones of radius $R_{isolation} = \sqrt{\eta^2 + \phi^2}$ respect to the (η - pseudorapidity)

upper plot \rightarrow signal events
 bottom plot \rightarrow background events

Isolation criteria ($R_{isolation} = 0.2$)
 E (of particles) = 0.5 GeV
 allows to separate 100% of QCD leptons with loss of 8% of signal events

Final S/B ratio = 3.6! $M_{inv}(l^+, l^-) > 0.9$
 S/B ratio = 9! For $M_{inv}(l^+, l^-) > 1.0$

Lepton (mu) isolation criteria

The plots show the distributions over the summarized energy of the final state particles in the cones of radius $R_{isolation} = \sqrt{\eta^2 + \phi^2}$ respect to the

upper plot \rightarrow signal events
 bottom plot \rightarrow background events

Isolation criteria ($R_{isolation} = 0.2$)
 E (of particles) = 0.5 GeV
 allows to separate 100% of Mini-bias bkg leptons with the loss of 8% of signal events

(after first 3 cuts applied (see the table) + cut $M_{inv}(l^+, l^-) > 0.9$)
