CENTER FOR THEORETICAL PHYSICS

Outline

- 1 Motivation and introduction
 - Background dependence in String & Field theory
 - Understanding a theory for all couplings
- 2 Background independence in Topological String Theory
 - Topological String Theory
 - Anomaly Equations
 - Geometric quantization
- 3 Polynomial structure of topological string
 - Genus zero data
 - Recursive relations

String Theories are 2d Conformal Field Theories

How to describe gravitational and gauge interactions in one theory?

- Possible solution: use 2 dimensional conformal field theory = 2d field theory with special features, very powerful, integrate over all 2d metrics

Partition functions contain are rich in information

What one wants to know

- Correlation functions, $\langle \phi_i \phi_j \phi_k \rangle$
- Possible deformations of the theory
- Critical exponents or scaling dimensions of operators, especially in statistical physics

Partition function Z

- contains a lot of information
- remember statistical physics
 $Z \sim \sum e^{-\beta H}$
- Field Theory
 $Z \sim \int_{\mathcal{X}} \mathcal{D}\phi e^{-S(\phi)}$, path integral

Spacetime metric is a coupling for 2d CFT

2 fields ϕ^1 & ϕ^2

$$\mathcal{L} = \underbrace{h^{\alpha\beta}}_{\text{2d metric}} \partial_\alpha \phi^1 \partial_\beta \phi^1 + h^{\alpha\beta} \partial_\alpha \phi^2 \partial_\beta \phi^2$$

could also consider

$$\mathcal{L} = \underbrace{g_{ij}(\phi^1, \phi^2)}_{\text{coupling from 2d point of view}} h^{\alpha\beta} \partial_\alpha \phi^i \partial_\beta \phi^j \Rightarrow \text{metric in 'Target' space}$$

String and Field theories depend on the background

Background is chosen in the moment we write down the action

- Target space characteristics, metric, topology, dimension
- Boundary conditions
- Couplings of the theory

Background dependence in String Theory

- Although string theory has spin 2 excitation, the graviton, current formulation just considers fixing a background metric and looking at fluctuations of it, described by gravitons
- It is a problem of *formulation* of the theory, we'd want to understand the background as a coherent state of closed strings for example

How can we understand a theory at all couplings?

What we usually do

- Identify relevant degrees of freedom at given energy
- Write down a theory of these degrees of freedom
- Adjust the couplings to experiments, e.g. α for Q.E.D.

Ideally

- Specify interaction pattern, symmetries
- Understand theory for all couplings
- Example exists:
Seiberg-Witten
understanding of
supersymmetric theories

Seiberg and Witten solved a class of supersymmetric theories

Seiberg Witten's solution for all couplings

- Knowing the theory for all couplings becomes a geometric problem, coupling parameter \Rightarrow geometry of an auxiliary space *Moduli Space*
- Knowing the singularities of the space = knowing where the effective description breaks down

Seiberg & Witten (1994)

$$\mathcal{L}_{int} \sim \tau w^2$$

$$\tau(u) \sim \theta(u) + \frac{i}{g^2(u)}$$

Singularity analysis
translate in maths

Is it possible to find moduli spaces for all backgrounds?

Moduli space for backgrounds?

- It's not just about couplings...
- How to specify the difference between one metric and another? topology? curvature?
- All possible boundary conditions? (In String theories this is the D-brane content)
- Sum over boundary condition? theories?
- difficult, approach through String Field Theory

Topological String Theories have close ties to maths

Topological String Theories have special features

- Symmetry $Q^2 = 0$, BRST-like symmetry $Q_B^2 = 0$ for fixing gauge symmetries
- Mappings (Fields on Σ_g) capture only the *topology* of the target space
- Path integral computable
- Partition function $Z_{\text{top}} = \exp\left(\frac{1}{2} \sum_g \lambda^{2g-2} F_g\right)$
- $\Rightarrow F_g$ central objects!

Topological String Theory captures Topology change of target space: A-Model

Size change

- Technically, changing the Kähler form which enters the definition of Volume form of the space
- There are families of spaces that only differ in that way
- Topological A-Model is a theory that captures these deformations

~ Deformations
of Kähler form

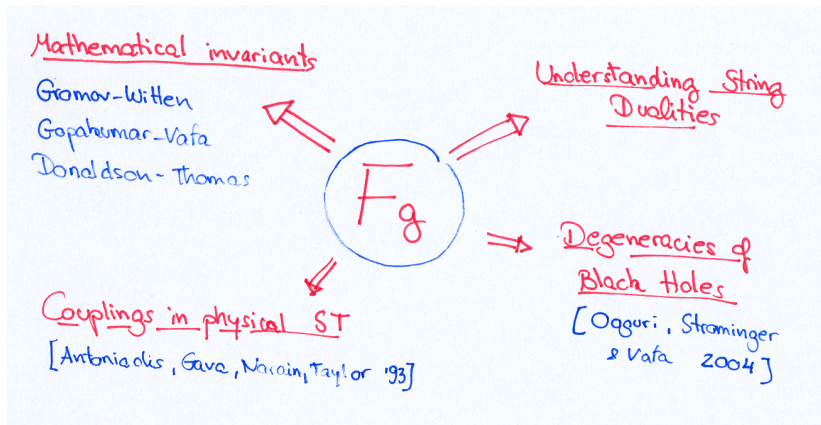

Topological String Theory captures Topology change of target space: B-Model

Shape change

- Actually: change of complex structure
- Related to the freedom in choosing what we call z and what we call \bar{z}
- Topological B-Model captures these changes

Topological String Theory establishes interesting connections

OK, then compute F_g

Strategies

- From the definition... cumbersome
- You know enough mathematics so that you can prove closed formulas... rare
- indirectly... the most common way, use features of the theory
- We'll have a closer look at a feature of topological string theory, holomorphic anomaly

Holomorphic anomaly equation gives recursive information

$$\bar{\partial} F_g = \frac{1}{2} \bar{C} (\mathbb{D} \mathbb{D} F_{g-1} + \sum_{r=1}^{g-1} \mathbb{D} F_r \mathbb{D} F_{g-r})$$

$\bar{\partial}$ is anti holomorphic
 $\underline{\mathbb{D}}$ is holomorphic
 $\mathbb{D} = \underline{\mathbb{D}} + \text{Connections}$

BCOV anomaly equation, Bershadsky, Cecotti, Ooguri & Vafa (1993)

- Relates recursively the partition function at genus g , F_g to partition functions at lower genus
- Theory is sensitive to choice of complex structure, i.e. what is holomorphic and what antiholomorphic \Rightarrow background dependence!

Anomaly can be written for all genera

$$Z = \exp \left[\frac{1}{2} \sum_{g=0}^{\infty} \lambda^{2g-2} F_g \right]$$

$\sum_g \Downarrow$ Anomaly

$$\left(\bar{\partial} - \lambda^2 \bar{c} \mathbb{D} \mathbb{D} \right) Z = 0$$

What kind of equation is this? looks familiar?

- We should look at geometric quantization!

Geometric quantization generalizes quantum mechanics

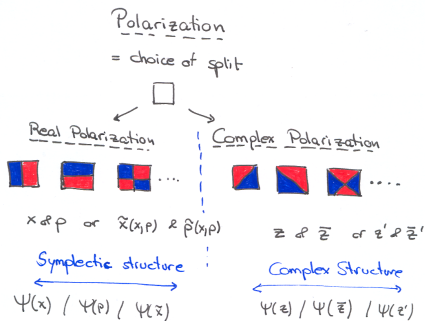

Give a geometric interpretation to quantization

- QM has phase space parameterized by x and p with Poisson bracket $\{.,.\}$
- Promote $f \rightarrow \hat{f}$, $\{.,.\} \rightarrow [.,.]$
- Throw away dependence on half of the coordinates $\psi(x)$ or $\psi(p)$, *Polarization*

Generalization

- Start with a space of dimension $2n$, that has a *symplectic* product
- Promote functions to operators (respecting the symplectic product)
- Throw away the dependence on half of the coordinates \Rightarrow *Polarization*

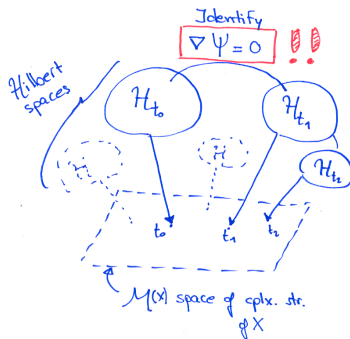

Wavefunctions only depend on half of the coordinates

Choosing a polarization means throwing away the dependence on half of the moduli

- We are familiar with this from quantum mechanics
- e.g. $\psi(x)$ or $\psi(p)$ or $\psi(a^\dagger)$

Identify all Hilbert spaces

Denote:

$$\Psi(z; t)$$

\in cplx. str.

Require that wavefunctions are covariantly constant

- Write out $\nabla \Psi = 0$

Anomaly equation is a wave equation

$$\nabla \Psi = 0$$

$$\left(\bar{\partial} - \frac{1}{4} (\bar{\partial} \mathcal{J} \omega^{-1}) \mathbb{D} \mathbb{D} \right) \boxed{\Psi} = 0$$

\uparrow \uparrow
 complex str. symplectic product

now compare to

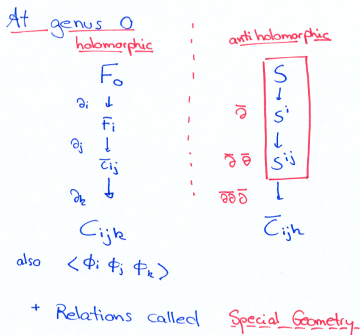

$$\left(\bar{\partial} - \lambda^2 \bar{c} \mathbb{D} \mathbb{D} \right) \boxed{Z_{\text{top}}} = 0$$

$\Rightarrow Z_{\text{top}}$ can be interpreted as
 a wavefunction in a \mathcal{H}
 obtained by geometric quantization

We need a different interpretation for Z_{top} , Witten (1993)

- Z_{top} is a wavefunction in a Hilbert space obtained by quantizing $H^3(X)$

Genus zero is governed by special geometry

Constraints of special geometry translate into existence of potentials

- The prepotential F_0 , the potential S for the antiholomorphic sector and their derivatives are the ingredients

F_g are polynomials in genus zero data

Our work Alim & Lange (2007) generalizing earlier work on the polynomial structure of the topological string for a special target space Yamaguchi & Yau (2004)

$$F_g = \text{Polynomial in } S, S^i, S^{\ddot{u}} + \text{hol.}$$

Proof: inductive

remember

$$\overline{\partial} F_g \sim \mathbb{D} \mathbb{D} F_{g-1} \text{ \& } \mathbb{D} F_{g' < g}$$

$$\Rightarrow \text{Show: } \left. \begin{array}{l} \mathbb{D} S^{\ddot{u}} = \dots \\ \mathbb{D} S^i = \dots \\ \mathbb{D} S = \dots \end{array} \right\} \begin{array}{l} \text{again} \\ \text{polynomial} \\ \text{in } S^{\ddot{u}}, S^i, S \end{array}$$

The polynomial structure facilitates computation

- however...

Still need further input

But:

$$\bar{\partial} F_g \rightarrow F_g$$

needs further information
(boundary conditions)

\Rightarrow Understand structure of
holomorphic part!

Still need to understand the holomorphic structure

- ongoing work...

Summary & Outlook

Summary

- Background dependence in String Theory
- Background independence in Topological String theory
- Polynomial structure of Topological Strings

Outlook

- Full understanding of polynomial structure, applications
- Connections to partition functions of Black Holes
- Understanding the Hilbert Space and the other states therein

Thanks to ...
